DEMONSTRATION AND PERFORMANCE ANALYSIS OF ROF BASED OFDM-PON SYSTEM FOR NEXT-GENERATION FABER OPTIC COMMUNICATION

Nadia Nowshin, Member, IEEE, A K M Arifuzzaman, Member, IEEE, Mohammed Tarique, Senior Member, IEEE

ABSTRACT

In this paper through the basic components of fiber optic communication, a novel transmission system for seamless integration of ROF (Radio Over Fiber) with centralized lightwave OFDM-PON based on an integrated external modulator is demonstrated. Here we have investigated the transmission performance of a modulation based on a proposed technique of Orthogonal Frequency Division Multiplexing (OFDM) for Next-Generation Passive Optical Network (NG-PON). The signal is generated by direct modulation of cost-effective and low bandwidth commercially available CW Lasers of 193.1 THz. The Downstream OFDM-PON transmission (5 Gbits/sec total, 2.5 Gbits/sec for each user) are experimentally demonstrated over a 50 km standard single mode fiber and additionally simulated through 1:2 splitter. And finally experimental results are analyzed based on optical signal spectrum in time-domain and compared with numerical results for different QAM (Quadrature Amplitude Modulation) and PSK (Phase Shift Keying) modulation schemes to demarcate concluding statements.

Orthogonal Frequency Division Multiplexing (OFDM), Passive Optical Network (PON), Radio-Over-Fiber (ROF), Optical Line Terminal (OLT), Optical Network Unit (ONU).

I. INTRODUCTION

In the era of 21st century rapid communication network, high application services like peer-to-peer (P2P) file sharing, video on demand services, High Definition Multimedia Television (HDTV), 3DTV are considered to be the most promising services, which requires a significant increase in bandwidth. And passive optical network (PON) is a promising solution for such communicative networks. It can provide different customers with simultaneous delivery of multiple-services over a common network [1-2]. But higher bandwidth requirement also increases the cost of transmission. So, the cost reduction in future PON systems will be the key challenge for operators’ deployment.

PON uses multicarrier modulation like orthogonal frequency division multiplexing (OFDM), which provides an opportunity of having an increased in bandwidth together with an affordable cost and this idea has recently become a suitable topic for many research works [3-4]. Due to its less Inter Symbol Interference (ISI), computational complexity and more robustness as compared to other multiplexing schemes and Orthogonal Frequency Division Multiplexing (OFDM) has been extensively used in wireless communication. OFDM dominated in wireless broadcast system such as Wi-Fi and WiMAX because of its robustness to multipath fading and high sub-carrier...
density through the digital FFT and IFFT [5]. As the underlying optical backbone for example PON become extensively deployed and recently cost-effective implementation of high-speed PON is of great interest [6-8]. And OFDM provided the better spectrum utilization and high transmission rate using low-cost optical components by M-ary modulation on its subcarriers, such as Phase-Shift-Keying (PSK) or Quadrature Amplitude Modulation (QAM) [3]. Besides that OFDMA (Orthogonal Frequency Division Multiple Access), a multi-user version of OFDM, is capable of assigning subsets of subcarriers to different users dynamically. Thus the total system bandwidth resources can be shared by all users [9]. Another promising alternative pathway toward ultrahigh capacity optical network is Coherent Optical Orthogonal Frequency Division Multiplexing (CO-OFDM). Most recently Coherent Optical OFDM (CO-OFDM) [10] and Direct-Detection Optical OFDM (DDO-OFDM) [11-14] has been proposed and investigated to offer many advantages for future high speed fiber transmission system.

The freshness of this paper lies in the fact that it demonstrates OFDM-PON architecture for downstream through M-ary QAM and M-aryPSK. Here we also analyzed the transmitted pulse spectrum and the received pulse spectrum at each ONU of the network with detailed parameters to find out the dispersion for different modulation technique.

This paper is organized as follows: Section II consists of the technical principle which is again segmented into OFDM technique implementation with QAM/PSK, Explanation of our proposed Passive optical Network (PON) and OFDM through PON. Then Section III describes the Experimental setup. After that the experimental parameters are extracted in Section IV. Section V states the simulated results and correspond discussions and finally Section VI wraps up with the Conclusion.

**II. TECHNICAL PRINCIPLE**

**A. OFDM WITH QAM / PSK**

In practice, OFDM systems are implemented using a combination of Fast Fourier Transform (FFT) and Inverse Fast Fourier Transform (IFFT) blocks as shown in Figure 1, that are mathematically equivalent versions of the DFT and IDFT respectively, but more efficient to implement.
An OFDM system considers the source symbols at the transmitter side (e.g., QAM or PSK symbols that can be presented in a single carrier system) to be in the frequency-domain. These symbols are used as inputs to an IFFT block that transfers the signal into time-domain. If the number of subcarriers used in the system is N then the IFFT takes in N symbols as an input at a time with a time period T second. The basic functions for an IFFT are N orthogonal sinusoids. These sinusoids each have a different frequency. Each of those input symbol behaves like a complex value for the corresponding sinusoidal basis function. And the output of the IFFT is the summation of all N sinusoids. After that, the output of the IFFT block passed through a digital-to-analog (D/A) converter and employed to modulate the carrier which results in the OFDM signal. And this process can be expected as an easy way to modulate data onto N orthogonal subcarriers. And at the receiver, an FFT block is used to bring the received signal back into the frequency domain. The received signal is initially down converted to the baseband signal and then passed through an analog-to-digital (A/D) converter in order to get the digitized values. The digital values are again portioned into blocks of length N and demodulated block by block by the FFT. Thus the original symbols are generated that were sent as inputs to the transmitter IFFT block. When the FFT output samples are plotted in the complex plane, they will form a constellation (such as QPSK, 16-QAM, 32-QAM etc.). The block diagram in Figure 1 illustrates the switch between frequency-domain and time-domain in an OFDM system.

**B. Passive Optical Network (PON)**

Fiber optics propagates light signals to transmit data or information. There are two important types of systems that make fiber optic broadband connections possible. These are active optical
networks and passive optical networks. Each of the two networks splits data/information and route them to the appropriate place, and each of the two networks has strengths and weaknesses as compared to the other.

Figure 2. Block diagram of a simple PON (Passive Optical Network)

An active optical system normally requires switching equipment that runs through electricity, such as, power combiners, multiplexers, demultiplexers, electrical decoders, routers or switch aggregators, to accomplish successful signal distribution to specific end user. There are a number of ways to perform the transmission and reception of information through switching. And in case of an active optical system, each end user may have a committed fiber running to his or her house. Whereas a passive optical network, on the other hand, does not require switching components running through electricity and instead of that they use optical splitters or forks to distribute and accumulate optical signals when they pass through the network. A passive optical network uses fiber optic equipment for certain part of the network that’s because it has been named as passive optical network. And another benefit of PON is that it uses electrically powered equipment only at the source and destination ends and can serve most probably up to 32 end users.

PON is a system that brings fiber optic cabling and signals to all or most of the way to the end user. Depending on where the PON terminates, the system can be described as FTTC (fiber-to-the-curb), FTTB (fiber-to-the-building), or FTTH (fiber-to-the-home).

Passive optical networks, or PONs, have some distinct advantages. They're efficient, in that each fiber optic strand can serve up to 32 users. PON has a low building cost relative to active optical networks along with lower maintenance costs. Because there are few moving or electrical parts, there's simply less that can go wrong in a PON.
A PON (Figure 2) consists of an Optical Line Termination (OLT) at the communication company's office, a number of end user lumps named as Optical Network Units (ONUs) and the combiners, fibers and splitters between them are referred to as the Optical Distribution Network (ODN). An ONU is a device or portion of the network that ends up the PON and provides customer service interfaces to the user. Some ONUs implement a separate subscriber unit to provide services such as telephony, Ethernet data, or video. The OLT provides the interface between the PON and the service providers network services which typically includes Internet Protocol (IP) traffic over gigabit/s, 10 Gbit/s, or 100 Mbit/s Ethernet, standard Time Division Multiplexed (TDM) interfaces such as SONET or Synchronous Digital Hierarchy (SDH) and Asynchronous Transfer Mode (ATM) User–network interface (UNI) at 155–622 Mbit/s etc. And the ONU that terminates the PON presents the native service interfaces to the user. These services comprised dynamically allocated bandwidth based plain telephone voice traffic/service, data traffic, voice traffic over internet protocol, video on demand, IP telephony services and/or telemetry (TTL, ECL, RS530, etc.).

Thus as a whole we can say that PON is a shared and distributed communication network, where the OLT collects all the voice/data traffic form ONUs and transmits them as a single stream of downstream traffic through the communication medium (fiber). But the impressive fact is that each ONU only retrieves the content of those packets that were addressed to it. Encryption and decryption is used to ensure the security of the system by precluding eavesdropping on downstream traffic. And the word “passive” simply designates the fact that once the signal starts moving through the network there is no power requirements or active electronic part requirement in that portion of the network.

C. OFDM with PON

Point-to-multipoint OFDM based passive optical network (PON) is expected to play a leading role in next-generation access. It offers bandwidth flexibility not only in between users but also between applications (Figure 3) which include mix of digital, analog, circuit and packet-switched, legacy and emerging applications.
In OFDM-PON system sub-carriers become transparent pipes for delivery of arbitrary signals like Ethernet, RF,T1/E1, mobile backhaul, VPN,IPTV, etc. For this purpose bandwidth is dynamically assigned to different services or different users are assigned different OFDM subcarrier within one OFDM band of total N subcarriers.

### III. EXPERIMENTAL SETUP

Our recommended OFDM-PON architecture based on the point-to-multipoint (PMP) topology is illustrated in Figure 4(a) and 4(b). The topology consists of the Optical Line Terminal (OLT)
situated at the Central Office (CO) and several Optical Network Units (ONUs) located at some particular distant location. Here the OLT comprises the fundamental blocks of RF OFDM transmitter and a RF-to-Optical(RTO) up-converter. And after passing through the optical link each ONU occupies an optical-to-RF (OTR) down-converter and a RF OFDM receiver. Here the subcarrier mapping enables spectrum division for different terminals and is essential for OFDM. Basically, the overall PON downstream bandwidth in baseband is 2.5 GHz generated by digital I-Q modulation is divided into several groups of orthogonal subcarriers. Dynamic allocation of subcarriers between ONUs is conducted intelligently by OLT. The OFDM block in scenario 1 of Figure 4 (a) has a FFT size of 64 and from which 52 subcarriers are used for data transmission.

Scenario 1-VOA- Voltage Optical Attenuator, ONU-Optical Network Unit

Figure 4 (a). Proposed PMPPONArchitecture (for scenario 1)
In the RF OFDM transmitter, the input digital data are first converted from serial to parallel block of bits consisting of information symbol where each symbol comprise multiple bits of M-arycoding. And, in our proposed model we used both M-aryQAM and M-aryPSK for constellation. The time domain OFDM signal is obtained through Inverse Fast Fourier Transform (IFFT) and a guard interval is inserted to avoid channel dispersion. The baseband OFDM signal can be up-converted to a RF passband through a RF IQ mixer. The subsequent RTO up-converter transforms the baseband signal to the optical domain using an optical IQ modulator comprising a Mach-Zehnder-modulator (MZM) with a 90 degree phase offset. Then finally the optical signal from the OLT is transmitted through a 50 km standard single mode fiber (SSMF) together with a 10-db optical attenuator (OA) and 1:2 optical splitter. The fiber used in this model is SMF-28 fiber with 17 ps/nm/km dispersion and an insertion loss of 0.2 dB/km at 1550 nm.

At the receiving end the optical signal travelling through the SSMF is converted back to RF OFDM signal by the OTR down-converter (scenario 2, Figure 4(b)). To maintain the received power is maintained between -6dBm and -19dBm by a VOA (Voltage Optical Attenuator), accounting a 4-5 dB from 50 km fiber and 9–22 dB attenuator loss. The received RF signal is detected by a PIN photodetector which converts the optical signal to an electrical one. Besides the PIN photodetector the ONU also contains a digital I-Q demux, followed by an FFT and a channel estimation/equalization.

**IV. EXPERIMENTAL PARAMETER EXTRACTION**

For Corning SMF-28 fiber,
If the operating wavelength =1550 nm, then the attenuation (A) at 1550 nm is =0.19db/km,
Transmitter output power (\( P_T \)) = 0 dBm, Total coupling loss (\( L_c \)) = 2×0.5= 1 dB,
Additional known Loss (\( L_A \)) = 0 dB, System margin, \( (M) = 6 \) dB and Receiver sensitivity (\( S_R \)) = -30 dBm.
So, Power budget = \( P_T - S_R = 0 \text{ dBm} - (-30) \text{ dBm} = 30 \text{ dBm} \).
Thus the maximum allowable fiber length = \( \frac{(30 - 7) \text{ dB}}{0.19 \text{ dB/km}} = 121 \text{ km} \).
As for the proposed model bit rate (R) = 2.5 Gbits/sec then the maximum allowable chromatic dispersion (\( \Delta \tau_{\text{max}} \)) = \( \frac{1}{4R} = \frac{1}{4 \times 2.5 \times 10^9} = 10^{-10} \text{ sec} = 100 \text{ ps} \).
Fiber dispersion co-efficient D (\( \lambda \)) = \( \frac{S_0}{4} \left( \lambda - \frac{\lambda_0^4}{\lambda^3} \right) \) = \( \frac{0.09}{4} \left( 1550 - \frac{(1312)^4}{(1550)^3} \right) \approx 17 \text{ ps/nm-km} \),
, where zero dispersion slope (\( S_0 \)) = 0.09 ps/\text{nm}^2, zero dispersion wavelength (\( \lambda_0 \)) = 1312 nm.
The RMS width of the transmitted pulse is \( T_{in} = \frac{T_{FWHM_{trans}}}{1.665} \text{ ps} \). (1)
And the RMS width of the received pulse at each ONU is \( T_{out} = \frac{T_{FWHM_{receive}}}{1.665} \text{ ps} \), (2)
, where \( T_{FWHM} \) is the FWHM width of the transmitted/received pulse.
And the RMS spectral width of the transmitted pulse or optical pulse,
\( \Delta \lambda(3) = \frac{\lambda^2 \sqrt{1 + C^2}}{2 \pi c T_{in}^2} \) (3)
, where chirp factor (\( C \)) = -6, wavelength (\( \lambda \)) = 1550 nm, speed of light (\( c \)) = \( 3 \times 10^8 \) m/s.
So, the RMS width of the fiber impulse response
\( (T_F) = L.D(\lambda).\Delta \lambda(4) \)
Thus the RMS width of the pulse at the far end of the optical fiber in each ONU is given by
\( T_{out} = \sqrt{T_{in}^2 + T_F^2} \) (5)

V. RESULT AND DISCUSSION

In this paper a software (Optisystem 10) based simulation is conducted to study the impact of different modulation schemes (M-ary PSK and M-ary QAM) on the downstream transmission (from OLT to different ONUs) performance of the proposed OFDM PON system. Total 52 subcarriers are used to create the OFDM signal. And the coefficient of each subcarrier will take complex values to carry M-ary modulations such QPSK or 16-PSK or 256-QAM.
From the transmitted and received optical spectra for QPSK (Figure 5) we can see that the FWHM width of the transmitted pulse (difference between point A and B) is $T_{\text{FWHM,trans}}=0.22\text{ ns} = 220\text{ ps}$ and FWHM width of the received pulse is $T_{\text{FWHM,receive}}=0.25\text{ns} = 250\text{ ps}$. So, from (eq.1) the RMS width of the transmitted pulse is $T_{\text{rms,trans}} = \frac{T_{\text{FWHM,trans}}}{\sqrt{\pi}} \approx 132\text{ ps}$. And from (eq.2) the RMS width of the received pulse is $T_{\text{rms,receive}} = \frac{T_{\text{FWHM,receive}}}{\sqrt{\pi}} \approx 150\text{ ps}$.

Now from eq.3 the RMS spectral width of the transmitted optical pulse ($\Delta \lambda$) = $\frac{\lambda}{2\pi c T_{\text{rms,trans}}}$ = 0.059 nm. So, the RMS width of the fiber impulse response ($T_F$) = L. D ($\lambda$). $\Delta \lambda$ = (50 km). (17 ps/nm-km). (0.059 nm) =50.15 ps. Thus the RMS width of the pulse at the far end of the optical fiber is $T_{\text{rms,trans}} + T_F = \sqrt{(132)^2 + (50.15)^2} = 138\text{ ps}$, which is nearly equal to the simulated value (150 ps).
Figure 6. Transmitted and Received Optical Spectrum for 16-QAM

Likewise the transmitted and received optical spectra for 16-QAM (Figure 6) shows that the FWHM width of the transmitted pulse is $T_{FWHM_{trans}} = 0.30$ ns = 300 ps and FWHM width of the received pulse is $T_{FWHM_{receive}} = 0.35$ ns = 350 ps. So, from (eq.1) the RMS width of the transmitted pulse is $T_{in} = \frac{T_{FWHM_{trans}}}{1.665} \approx 180$ ps. And from (eq.2) the RMS width of the received pulse is $T_{out} = \frac{T_{FWHM_{receive}}}{1.665} \approx 210$ ps. Now from eq.3 the RMS spectral width of the transmitted optical pulse ($\Delta \lambda$) = $\frac{\lambda^2}{2\pi c T_{in}} = 0.0431$ nm. So, the RMS width of the fiber impulse response ($T_F$ = L. D (\lambda). $\Delta \lambda$ = (50 km). (17 ps/nm-km). (0.0431 nm) = 36.635 ps. Thus the RMS width of the pulse at the far end of the optical fiber is $T_{out} = \sqrt{T_{in}^2 + T_F^2} = \sqrt{(180)^2 + (36.635)^2} = 184$ ps.

For 64-QAM (Figure 7), $T_{FWHM_{trans}} = 0.31$ ns = 310 ps, $T_{FWHM_{receive}} = 0.37$ ns = 370 ps. Thus $T_{in} = \frac{T_{FWHM_{trans}}}{1.665} \approx 186$ ps and $T_{out} = \frac{T_{FWHM_{receive}}}{1.665} \approx 222$ ps. And $\Delta \lambda = \frac{\lambda^2}{2\pi c T_{in}} = 0.0417$ nm, $T_F = L. D (\lambda). \Delta \lambda = (50 \text{ km}). (17 \text{ ps/nm-km}). (0.0417 \text{ nm}) = 35.45$ ps. Thus the RMS width of the pulse for QAM 64 at the far end of the optical fiber is $T_{out} = \sqrt{T_{in}^2 + T_F^2} = \sqrt{(186)^2 + (35.45)^2} = 189$ ps.
Figure 7. Transmitted and Received Optical Spectrum for 64-QAM.

Figure 8. Transmitted and Received Optical Spectrum for 256-QAM
And according to Figure 8, 256-QAM has $T_{\text{FWHM,trans}} = 0.32 \text{ ns} = 320 \text{ ps}$, $T_{\text{FWHM,receive}} = 0.39 \text{ ns} = 390 \text{ ps}$. Thus $T_{\text{in}} = \frac{T_{\text{FWHM,trans}}}{1.665} \text{ ps} \approx 192 \text{ ps}$ and $T_{\text{out}} = \frac{T_{\text{FWHM,receive}}}{1.665} \text{ ps} \approx 234 \text{ ps}$. And $\Delta \lambda = \frac{\lambda^2 (1 + c^2)}{2 \pi c T_{\text{in}}} = 0.0404 \text{ nm}$, $T_F = L \cdot D (\lambda)$. $\Delta \lambda = (50 \text{ km}) \cdot (17 \text{ ps/nm-km}) \cdot (0.0404 \text{ nm}) = 34.34 \text{ ps}$. So, the calculated value of $T_{\text{out}} = \sqrt{T_{\text{in}}^2 + T_F^2} = \sqrt{(192)^2 + (34.34)^2} = 195 \text{ ps}$.

![Transmitted Optical Spectrum for 16-PSK](image1)

![Received Optical Spectrum for 16-PSK](image2)

Figure 9. Transmitted and Received Optical Spectrum for 16-PSK

For 16-PSK (Figure 9), $T_{\text{FWHM,trans}} = 0.21 \text{ ns} = 210 \text{ ps}$, $T_{\text{FWHM,receive}} = 0.27 \text{ ns} = 270 \text{ ps}$. Thus $T_{\text{in}} = \frac{T_{\text{FWHM,trans}}}{1.665} \text{ ps} \approx 126 \text{ ps}$ and $T_{\text{out}} = \frac{T_{\text{FWHM,receive}}}{1.665} \text{ ps} \approx 162 \text{ ps}$. And $\Delta \lambda = \frac{\lambda^2 (1 + c^2)}{2 \pi c T_{\text{in}}} = 0.0616 \text{ nm}, T_F = L \cdot D (\lambda)$. $\Delta \lambda = (50 \text{ km}) \cdot (17 \text{ ps/nm-km}) \cdot (0.0616 \text{ nm}) = 52.36 \text{ ps}$. Thus the RMS width of the pulse for 16-PSK at the far end of the optical fiber is $T_{\text{out}} = \sqrt{T_{\text{in}}^2 + T_F^2} = \sqrt{(126)^2 + (52.36)^2} = 136 \text{ ps}$. 
According to Figure 10, 64-PSK has $T_{\text{FWHM,trans}} = 0.35 \text{ ns} = 350 \text{ ps}$, $T_{\text{FWHM,receiver}} = 0.42 \text{ ns} = 420 \text{ ps}$.

Figure 11. Transmitted andReceived Optical Spectrum for 256-PSK
Thus \( T_{\text{in}} = \frac{T_{\text{FWHM,trans}}}{1.665} \approx 210 \text{ps} \) and \( T_{\text{out}} = \frac{T_{\text{FWHM,receive}}}{1.665} \approx 252 \text{ ps} \). And \( \Delta \lambda = \frac{\lambda^2 (1+C^2)}{2 \pi T_{\text{in}}} = 0.0369 \text{ nm} \), \( T_F = L \cdot D (\lambda) \), \( \Delta \lambda = (50 \text{ km}) \). (17 \text{ ps/nm-km}) \cdot (0.0369 \text{ nm}) = 31.37 \text{ ps} \). So, the calculated value of \( T_{\text{out}} = \sqrt{T_{\text{in}}^2 + T_F^2} = \sqrt{(210)^2 + (31.37)^2} = 213 \text{ ps} \).

And, finally Figure 11 for 256-PSK shows that, \( T_{\text{FWHM,trans}} = 0.33 \text{ ns} = 330 \text{ ps} \), \( T_{\text{FWHM,receive}} = 0.41 \text{ ns} = 410 \text{ ps} \). Thus \( T_{\text{in}} = \frac{T_{\text{FWHM,trans}}}{1.665} \approx 198 \text{ ps} \) and \( T_{\text{out}} = \frac{T_{\text{FWHM,receive}}}{1.665} \approx 246 \text{ ps} \). And \( \Delta \lambda = \frac{\lambda^2 (1+C^2)}{2 \pi T_{\text{in}}} = 0.0392 \text{ nm} \), \( T_F = L \cdot D (\lambda) \), \( \Delta \lambda = (50 \text{ km}) \). (17 \text{ ps/nm-km}) \cdot (0.0392 \text{ nm}) = 33.32 \text{ ps} \). Thus the RMS width of the pulse for 16-PSK at the far end of the optical fiber is \( T_{\text{out}} = \sqrt{T_{\text{in}}^2 + T_F^2} = \sqrt{(198)^2 + (33.32)^2} = 201 \text{ ps} \).

In Figure 5 to Figure 11 we epitomized the transmitted and received optical pulse at the far end of the Optical fiber (at different ONU’s) for different QAM and for different PSK modulation scheme through an Optical Time Domain Analyzer (OTDA). And we can see that by increasing the number of bits per symbol from 2 to 8 per symbol (for QPSK to 256-QAM or 256-PSK) we can increase the OFDM transmission rate with a certain amount of dispersion (that means the received pulses gets wider than the transmitted one).

Here Table 1 shows the overall summary of the dispersion/ pulse broadening quantity at the far end of the optical fiber for different modulation schemes. From the table we can see that for QPSK the measured dispersion and the difference between the calculated and measured value is minimum but as we move on to higher order modulations (from 16-QAM up to 256-QAM or from 16-PSK up to 256-PSK) the dispersion increases significantly. And among all of the modulation QPSK is the best choice for our proposed model.
VI. CONCLUSION

In this paper we proposed a novel light-wave centralized passive optical network (PON) based on various modulation schemes and simulated through fiber optic based simulation software called Optisystem. Previous research works related to PON derived bit error rate (BER) from the measured vector magnitude (EVM) [15] and compared the performance among different m-QAM modulation techniques but never showed the performance measurements for both PSK and QAM together based on dispersion factor with numerical analysis. But in our paper we considered and compared the dispersion through both numerical analysis and simulated results for both m-PSK and m-QAM. The symmetric OFDM-PON traffic (2.5 Gb/s for each ONU) is experimentally portrayed over 50 km single mode fiber followed by an additional 1:2 optical splitter. It’s a simple OFDM based PON architecture that has proven viability as a flexible, high-speed and cost-effective network and could be a potential choice for future PON systems since the data rate of the present PONs can be upgraded easily without significantly changing the network infrastructure.
