#### Abstract

: This paper discusses the linear complexity property of binary sequences generated using matrix recurrence relation defined over $Z_{4}$. Generally algorithm to generate random number is based on recursion with seed value/values. In this paper a linear recursion sequence of matrices or vectors over $Z_{4}$ is generated from which random binary sequence is obtained. It is shown that such sequences have large linear complexity.

Keywords
Matrix Recurrence Relation, Random Sequence, Linear Complexity, $Z_{4}$ Sequence, Random numbers

## 1. INTRODUCTION

Today's modern cryptography needs to deal with many aspects of security issues.In addition to providing confidentiality, it has to provide data integrity, authentication and non repudiation [1].Ever increasing computing power of potential attackers endangers even well-researched encryption algorithms [2].

Cryptography systems can be broadly classified into symmetric-key systems such as DES, AES and RC4 that use a single key that both the sender and recipient have to encrypt and decrypt respectively. Public-key or asymmetric systems such as RSA, ElGamal and Elliptic curve cryptograchy that use two keys, a public key known to everyone and a private key that only the recipient of messages uses [3], [4, [5]. Symmetric cryptosystem is usually divided into block ciphers and stream ciphers. Block ciphers operate with a fixed transformation on large blocks of plain-text data; stream ciphers operate with a time-varying transformation on individual plaintext digits [1], [5].This classification is not absolute, and any block cipher can be used as a
stream cipher by using certain modes of operation. Cipher Feedback mode (CFB), Output Feedback mode and Counter mode operation on block cipher system can be used to turn a block cipher into a stream cipher. They can be proven secure under the assumption that the block cipher is secure [1], [3], [4].

In block cipher data is devided into blocks and encrypt and decrypt block wise, where in a stream cipher encryption or decryption is bit-by-bit or character by character. Both block ciphers and stream ciphers are in common use today. Generally in stream encryption system, a binary message is encrypted by adding bit by bit modulo 2 a binary random sequence called key sequence. Stream cipher system has the advantage that both encryption and decryption occurs at real time. Stream ciphers are especially prevalent in business and military applications [2], [3], [4] [5] [6], [7].

Security of stream cipher system depends on the randomness properties of the sequence called key sequence. Therefore key sequence generator is very important building block for stream cipher system. A random bit generator can be used to generate binary random bit sequences with desirable statistical properties which are important in cryptographic applications. The need for design of efficient and secure pseudorandom sequence generators remains an ongoing challenge and an important field in cryptographic research up to the present day.

A method of generation of random binary sequences using matrix recurrence relation defined over $\mathrm{Z}_{4}$ is discussed in [8].There are standard tests like FIPS-1 and NIST-SP-800-2 revision 1 [9] test suites to test the randomness properties of binary sequences. It is shown in [8] that sequences generated using matrix recurrence relation pass these test suites. It is also found that such sequences exhibit good autocorrelation and cross correlation properties [10].

In this correspondence, we discuss the generation of random sequence defined over $\mathrm{Z}_{4}$ using matrix recurrence relation and corresponding binary sequence is derived from it. Linear complexity of the binary sequences so generated is determined using Massey - Berlekamp algorithm [11] and results are analyzed. It is shown that such sequences exhibit large linear complexity which is desirable characteristics of random sequences required for key sequences in stream cipher systems.

## Organization of the rest of the paper:

In Section 2 we introduce random sequence generator. Section 3 introduces a method of generation of random sequence using matrix recurrence relation defined over $Z_{4}$. Section 4 discusses the results. Section 5 contains concluding remarks.

## 2. RANDOM SEQUENCE GENERATORS

Random binary sequences are used as running key sequence in stream cipher system. Here message is in the form of binary sequence is encrypted by adding bit by bit modulo 2 a binary random sequence called key sequence and decrypted at the receiver using the same random key sequence generated at the receiver.

Linear Feedback Shift Registers (LFSRs) are important building blocks for generating key sequences. Maximum length sequences called m- sequences generated by an n stage Linear Feedback Shift Registers have very good randomness properties such as long period, ( $2^{\mathrm{n}}-1$ ), balance, ideal autocorrelation and good statistical properties which are desirable characteristic[6]. Also LFSR can be easily implemented both in hardware and software.However $m$-sequences have low linear complexity. For an m-sequence of length $2^{n}-1$ the linear complexity is n . In this case only 2 n consecutive bits are required to determine the feedback polynomial of the LFSR and hence the entire sequence. In the practical stream cipher designs, a large linear complexity of the key stream is obtained by a nonlinear transformation of the LFSR output sequence or nonlinear feedback shift register.

The use of non linear feedback mechanism to produce pseudorandom sequence is discussed in [3], [4]. Some of the methods of transformation define three general design categories: combination generators; filter generators and clock controlled generators [3].

The linearity complexity properties of LSFR's can be improved by feeding the outputs of several parallel LFSRs into a non-linear Boolean function to form a combination generator. The various properties of such a combining function are critical for ensuring the security of the resultant scheme, like avoiding correlation attacks.

Clock controlled generators [17] serve the function of introducing non-linearity in LFSRs. This non-linearity is achieved by having LFSR clocked irregularly by being driven by the output of some other LFSR. Several generators based on this principle have been proposed like stop-andgo, alternating step generator [12] and the shrinking generator [3], [4], [13], [14][15][16]

Another approach of improving the linearity complexity of sequence generated by LFSR is to use Filtering Boolean functions [5]. Although, not sufficient to be resistant enough against several attacks, certain characteristics are supposed to be necessary in stream ciphers with this structure. These characteristics include: high non-linearity, balance, and algebraic immunity [17].
Some of the widely used random sequence generators are generator based on recurrence modulo 2 [11],[18], linear feedback shift register generator (LFSR) [4], [20],[21],[22], feedback with carry shift registers (FCSR) [23],[24], nonlinear combination generators [3],[4], non linear feedback shift registers (NLFBSR) [3],[4], Marsaglia random number generators [25]-[26], and elliptic curve based pseudorandom random sequence generator [28] etc. Examples of cryptographically secure pseudorandom bit generators are RSA pseudorandom bit generator [29], Micali-Schnorr pseudorandom bit generator [30, 31], Blum-Blum-Shub pseudorandom bit generator ( $\mathrm{x}^{2} \bmod \mathrm{~N}$ generator) [32], [33]. Generally in all these schemes a random sequence is generated using seed key.Generally stream cipher systems are fast and easy to implement both in hardware and software.
The proposed scheme describes a method of obtaining binary sequences with large linear complexity.

## 3. PROPOSED RANDOM SEQUENCE GENRATOR USING MATRIX RECURRENCE RELATION

The proposed random sequence generator defined over $\mathrm{Z}_{4}$ is based on Matrix Recurrence Relation defined by,
$\mathrm{U}_{\mathrm{j}}=\sum_{\mathrm{i}=0}^{\mathrm{n}-1} \mathrm{~A}_{\mathrm{i}} \mathrm{U}_{\mathrm{j}-\mathrm{i}-1}, \quad \mathrm{j} \geq \mathrm{n}$, arithmetic modulo 4
Where $\mathrm{A}_{\mathrm{i}} \mathrm{s}, \mathrm{i}=0,1, \ldots \ldots \ldots \ldots, \mathrm{n}$-1are $\mathrm{k} \times \mathrm{k}$ matrices called co-efficient matrices, $\mathrm{U}_{\mathrm{i}} \mathrm{s}, \mathrm{i}=$ $0,1, \ldots \ldots \ldots \ldots \ldots, n-1$ are $k \times k$ initial matrices called seed matrices over $Z_{4}$.With $U_{0}, U_{1}$, $\mathrm{U}_{2}, \ldots \ldots \ldots \ldots \ldots \ldots . \mathrm{U}_{\mathrm{n}-1}$ known, $\mathrm{U}_{\mathrm{n}}, \mathrm{U}_{\mathrm{n}+1}, \ldots \ldots \ldots \ldots$. satisfies the recurrence relation (1), where n is called order of the recurrence relation.

A Vector recurrence relation can also be defined as follows
$\mathrm{V}_{\mathrm{j}}=\sum_{\mathrm{i}=0}^{\mathrm{n}-1} \mathrm{~A}_{\mathrm{i}} \mathrm{V}_{\mathrm{j}-\mathrm{i}-1}, \quad \mathrm{j} \geq \mathrm{n}$, arithmetic modulo 4
Where, as in equation (1) $\mathrm{A}_{\mathrm{i}} \mathrm{s}, \mathrm{i}=0,1, \ldots, \mathrm{n}-1$ are $\mathrm{k} \times \mathrm{k}$ matrices called co-efficient matrices. $\mathrm{V}_{\mathrm{i}} \mathrm{s}$, $\mathrm{i}=0,1, \ldots, \mathrm{n}-1$ are $\mathrm{k} \times 1$ vector called seed values . With $\mathrm{V}_{0}, \mathrm{~V}_{1}, \mathrm{~V}_{2}, \ldots \ldots \mathrm{~V}_{\mathrm{n}-1}$ known, $\mathrm{V}_{\mathrm{n}}, \mathrm{V}_{\mathrm{n}+1}, \ldots \ldots$. satisfies the recurrence relation (2) .

Based on recurrence relation (1), with $n$ arbitrary initial $k \times k$ seed matrices $\mathrm{U}_{0}, \mathrm{U}_{1}, \mathrm{U}_{2}, \ldots \ldots . . \mathrm{U}_{\mathrm{n}}$ ${ }_{1}$, random sequence of $\mathrm{k} \times \mathrm{k}$ matrices $\mathrm{U}_{0}, \mathrm{U}_{1}, \mathrm{U}_{2}, \ldots \ldots \mathrm{U}_{\mathrm{j}}$ over $\mathrm{Z}_{4}$ is generated as follows
$\mathrm{U}_{\mathrm{n}}=\mathrm{A}_{0} \mathrm{U}_{\mathrm{n}-1}+\mathrm{A}_{1} \mathrm{U}_{\mathrm{n}-2}, \ldots \ldots . .+\mathrm{A}_{\mathrm{n}-1} \mathrm{U}_{0}$ modulo 4,
$\mathrm{U}_{\mathrm{n}+1}=\mathrm{A}_{0} \mathrm{U}_{\mathrm{n}}+\mathrm{A}_{1} \mathrm{U}_{\mathrm{n}-1}, \ldots \ldots \ldots+\mathrm{A}_{\mathrm{n}-1} \mathrm{U}_{1}$, modulo 4

In general for $\mathrm{j} \geq \mathrm{n}$
$\mathrm{U}_{\mathrm{j}}=\mathrm{A}_{0} \mathrm{U}_{\mathrm{j}-1}+\mathrm{A}_{1} \mathrm{U}_{\mathrm{j}-2}, \ldots \ldots \ldots+\mathrm{A}_{\mathrm{n}-1} \mathrm{U}_{\mathrm{j}-\mathrm{n}}$, modulo 4
It can be shown that the sequence generated is strictly periodic if $k \times k$ coefficient matrix $A_{n-1}$ is nonsingular [8].

### 3.1. General Case of Sequence over $Z_{4}$

The method of generation of sequences of matrices and sequences of vectors over $\mathrm{Z}_{4}$ is described below.

## Case I: Generation of Sequences of Matrices over $\boldsymbol{Z}_{4}$

In this case the $n$ coefficients $A_{i} s, i=0,1 \ldots \ldots \ldots . n-1$ are $k \times k$ matrices over $Z_{4}$ which are arbitrarily chosen with $\mathrm{A}_{\mathrm{n}-1}$ nonsingular to get strictly periodic sequence. The n initial matrices $U_{i} s, i=0,1 \ldots \ldots \ldots . . n-1$ are also $k \times k$ matrices over $Z_{4}$. Random sequence of $k \times k$ matrices is generated using equation (1) by randomly selecting the coefficient matrices and initial matrices over $\mathrm{Z}_{4}$. Different sequences are generated for different coefficients and initial matrices. The properties of the sequences generated depend on coefficient matrices, initial seed matrices and n , order of recurrence relation given in expression (1).

## To obtain Binary Sequence from Matrix Sequence over $Z_{4}$

Coefficient matrices $\mathrm{U}_{\mathrm{i}} \mathrm{s}$ are over $\mathrm{Z}_{4}$, the elements are from the set $\{0,1,2,3\}$. Sequence over $\mathrm{Z}_{4}$ can be derived from the sequence of $k \times k$ matrices by concatenation of the rows of $U_{i} s$.Then a sequence of $N$ matrices each having $k^{2}$ elements from $Z_{4}$ gives rise to a sequence of $N k^{2}$ elements over $Z_{4}$. By representing the elements $0,1,2$, and 3 in binary as $00,01,10$, and 11 respectively the length of the corresponding binary sequence is $2 \mathrm{Nk}^{2}$.

Consider $\mathrm{k} \times \mathrm{k}$ seed matrices, each having $\mathrm{k}^{2}$ elements.
The number of possible seed matrices over $Z_{4}$ for each stage $=4^{k^{* *}{ }_{2}}$
For $\mathrm{k}=2$, number of possible matrices $=4^{4}=256$
For $n$ stages the number of possible seed matrices over $Z_{4}$ is $4^{n k * *}$. If all the possible states are in one cycle, then the corresponding length of sequence is $4^{\mathrm{nk} * 2}$, which is the maximum possible length. Corresponding maximum possible length of binary sequence is equal to $2\left(4^{\mathrm{nk}{ }^{* * 2}}\right)$. However the actual length of the sequence generated is always less than the maximum possible value and depends on the coefficient matrices and seed matrices.

## Case 2: Generation of Sequence of Vectors over $Z_{4}$

By having $k \times k$ coefficient matrices as above and with the initial values from a set of $k \times 1$ vectors over $\mathrm{Z}_{4}$ instead of $\mathrm{k} \times \mathrm{k}$ matrices, the sequences of $k \times 1$ vectors over $\mathrm{Z}_{4}$ are generated. The number of possible seed vectors for one stage is $4^{\mathrm{k}}$ and for n stages it is $4^{\mathrm{kn}}$.

## To obtain Binary Sequence from Vector Sequence over $Z_{4}$

The recurrence relation given by equation (2) is used to generate sequence of $k \times 1$ vectors $\left\{\mathrm{V}_{\mathrm{i}}\right\}$, over $\mathrm{Z}_{4}$. The seed values $\mathrm{V}_{0}, \mathrm{~V}_{1}, \mathrm{~V}_{2}, \mathrm{~V}_{\mathrm{n}-1}$ are $\mathrm{k} \times 1$ vectors over $\mathrm{Z}_{4}$. Seed vectors along with known n coefficient matrices are used to obtain random vector sequence $\left\{\mathrm{V}_{\mathrm{i}}\right\}$. As mentioned earlier with $A_{n-1}$, a $k \times k$ nonsingular coefficient matrix, the sequence generated is strictly periodic. Sequence over $\mathrm{Z}_{4}$ is generated by concatenating the transpose of vectors in sequence $\left\{\mathrm{V}_{\mathrm{i}}\right\}$.

Consider vector sequence of length N .The corresponding sequence over $\mathrm{Z}_{4}$ is then of length Nk . The corresponding binary sequence is of length 2 Nk . For a vector sequence of size $k \times 1$, with $n$ number of stages the maximum possible length of the sequence will be equal to $4^{\mathrm{nk}}$ and the corresponding maximum possible length of binary sequence is equal to $2\left(4^{\mathrm{nk}}\right)$.

In this case also the actual length of sequences depends on number of stages $n$, choice of coefficient matrices and seed values and is less than the maximum possible value.

### 3.2. Linear Complexity Measure

One of the most useful concepts in the study of key sequences used in stream ciphers is that of linear complexity. The linear complexity of a binary sequence is defined as the length of the shortest linear feedback shift register that generates it. If a sequence has small linear complexity, then the synthesis of a linear equivalent of the sequence generator becomes computationally feasible. The linear complexity of a finite sequence is determined using Massey -Berlekamp algorithm [11]. The algorithm is briefly described below.

## Algorithm:

INPUT: A binary sequence $s_{n}=s_{0}, s 1, s 2, \ldots \ldots, s_{n-1}$ of length $n$.

OUTPUT: Linear complexity L( $\mathrm{s}^{\mathrm{n}}$ ) of $\mathrm{s}_{\mathrm{n}}, 0 \leq \mathrm{i} \leq \mathrm{n}$.
Initialization: $\mathrm{C}(\mathrm{D})=1=0, l=0, \mathrm{~m}=-1, \mathrm{~B}(\mathrm{D})=1, \mathrm{~N}=0$.
2. While $(\mathrm{N}<\mathrm{n})$ do the following:
2.1 Compute the next discrepancy d.

$$
\mathrm{d}=\left(\mathrm{s}_{\mathrm{N}}+\sum_{\mathrm{i}=1}^{\mathrm{L}} \mathrm{c}_{\mathrm{i}} \mathrm{~s}_{\mathrm{N}-1}\right) \bmod 2,
$$

2.2 If $\mathrm{d}=1$ then do the following:
$\mathrm{T}(\mathrm{D})=\mathrm{C}(\mathrm{D}), \mathrm{C}(\mathrm{D})=\mathrm{C}(\mathrm{D})+\mathrm{B}(\mathrm{D}) \mathrm{D}^{\mathrm{N}-\mathrm{m}}$.
If $\mathrm{L} \leq \mathrm{N} / 2$ then $\mathrm{L}=\mathrm{N}+1-\mathrm{L}, \mathrm{m}=\mathrm{N}, \mathrm{B}(\mathrm{D})=\mathrm{T}$ (D).
$2.3 \mathrm{~N}=\mathrm{N}+1$.
3. Return (L).

Where $C(D)$ is connection polynomial, $L$ is linear complexity.
It is desirable that random sequence which can be used as key sequence in stream cipher systems to have a large linear complexity. The necessary (but not sufficient) condition to be secure in running key stream cipher is to have large linear complexity [11], [34], [35]..

Even for a given order n , for different arbitrarily chosen n coefficient matrices and seed values, the generated sequence of length m, need not necessarily have same linear complexity. Further
just by knowing $n$ coefficient matrices and initial values, linear complexity cannot be predicted .Hence linear complexity can be treated as a random variable. Thus to study the statistical behavior of the linear complexity, number of sequences are generated and their linear complexity is computed. From these data we compute Mean, $\mu_{\mathrm{x}}$ Variance, $\sigma_{\mathrm{x}}{ }^{2}$, and Standard deviation, $\sigma_{x}$ of linear complexity. The definition of Mean, Variance, and Standard deviation are available in [37].The definitions are repeated here.

## Mean

Let $X_{1}, X_{2}, X_{3} \ldots X_{N}$ be $N$ linear complexity values of N sequence of same length.The mean value, $\mu_{\mathrm{x}}$ or expected value of linear complexity is defined as

Mean $=\mu_{x}=\frac{1}{N} \sum_{i=1}^{N} X_{i}$

## Variance and standard deviation, $\sigma_{\mathrm{x}}{ }^{2}$

Variance of random variable X is a measure of how far the value of random variable deviates from its mean value. It is defined as
$\sigma_{x}^{2}=\frac{\sum_{i=1}^{N}\left(X_{i}-\mu_{x}\right)^{2}}{N}$
Very small value of variance indicates that $X$ takes values almost equal to $\mu_{x}$. The standard deviation $\sigma_{\mathrm{x}}$ is the positive square root of its variance $\sigma_{\mathrm{x}}{ }^{2}$. Standard deviation is a widely used measure of the variability or dispersion from mean value. It shows how much variation there is from the "average" (mean or expected) value. A low standard deviation indicates that the values tend to be very close to the mean, whereas high standard deviation indicates that the values are spread out over a large range of values, around the mean value.

Through simulation it is seen that by proper choice of size, k of matrix and number of stages, n it is possible to generate random binary sequences of large linear complexity.

## 4. SIMULATION RESULTS AND DISCUSSIONS

In general the binary sequence generated will have its linear complexity which depends on
i) $\quad \mathrm{n}$, the order of recurrence relation
ii) choice of $n$ coefficient matrices and
iii) the n seed value

### 4.1. CASE 1: Matrix Sequences and Corresponding Binary Sequences

In the following studies $\mathrm{k}=2$ is chosen. From equation (6), the number of $2 \times 2$ matrices over $\mathrm{Z}_{4}$ is 256 .As n increases the linear complexity of the sequence also increases. This is verified by means of computer simulation. For $n=5,10,15,20,25$ and 30 , the corresponding number of $2 \times 2$ coefficient matrices are arbitrarily chosen from a set of $256,2 \times 2$ matrices. Likewise the $n$ seed values are also chosen arbitrarily. In each case, 10 different sequences of length $\mathrm{m}=5000$ bits are considered. Linear complexities of these 10 sequences are computed using BerlekampMassey algorithm [11].The statistical behavior of linear complexity X is found by computing its mean $\mu_{\mathrm{x}}$, variance, $\sigma_{\mathrm{x}}{ }^{2}$ and standard deviation , $\sigma_{\mathrm{x}}$ after the linear complexities of 10 sequences are computed. The results are tabulated in Table 1.

Columns of Table 1shows the computed linear complexity of generated sequences using recurrence relation of order $\mathrm{n}=5, \mathrm{n}=10,15,20,25$ and 30 respectively. It is observed from the Table 1 that the mean linear complexity $\mu_{\mathrm{x}}$ for sequences of length 5000 bits for $\mathrm{n}=5$ are found to be 556. Similarly the mean linear complexities $\mu_{\mathrm{x}}$, for $\mathrm{n}=10,15,20,25$, and 30 are found to be 1875.8, 2495.8, 2493, 2498.3, 2499.3 respectively. The corresponding variance $\sigma_{\mathrm{x}}{ }^{2}$ is found to be 125.7777, 126.4, $130.4889,52,11.3444$ and 0.9111 respectively. Likewise the corresponding standard deviation $\sigma_{\mathrm{x}}$ is found to be11.2150, 11.2427, 11.4231, $7.2111,3.3681$ and 0.6749 respectively. From these results it is evident that the linear complexity value is increasing with the order n of recurrence relation and approaches $\mathrm{m} / 2$ for $\mathrm{n} \geq 15$. Correspondingly variance, and standard deviation decreases. This implies that the sequences generated have mean value of linear complexity $\mu_{\mathrm{x}}$ almost equal to $\mathrm{m} / 2$ with high probability for $\mathrm{m}=5000$ bits and $\mathrm{n} \geq 15$.

Similarly Table 2 and Table 3, list the linear complexities $X$, mean $\mu_{\mathrm{x}}$, variance $\sigma_{\mathrm{x}}{ }^{2}$ and standard deviation $\sigma_{\mathrm{x}}$ for sequences of length 10000 bits and 20000 bits respectively, for different $\mathrm{n}=$ $5,10,15,20,25$ and 30. It is seen from Table 2 and Table 3 that for $m=10000$ and 20000 and for $\mathrm{n} \geq 20$ the linear complexity approaches $\mathrm{m} / 2$ which is desirable for random sequences [36].

The variation of mean $\mu_{\mathrm{x}}$, variance $\sigma_{\mathrm{x}}{ }^{2}$ and standard deviation $\sigma_{\mathrm{x}}$ with different m and n are depicted in Figure.1, Figure. 2 and Figure.3.respectively. For different length of sequence m $=5000,10000$ and 20000 it is also seen that the values of variance and standard deviation are decreasing as $n$ increases.

From the above results it is seen that for $\mathrm{n} \geq 15$ the mean value of linear complexity $\mu_{\mathrm{x}}$ is almost equal to $\mathrm{m} / 2$ and hence the generated sequences have linear complexity $\mathrm{m} / 2$ with high probability for $m=5000$ bits. It is also seen that variance $\sigma_{x}{ }^{2}$ and standard deviation $\sigma_{x}$ are small. The same behavior of linear complexity, variance and standard deviation of linear complexity are observed for $\mathrm{m}=10000$ and 20000 bits. These are depicted in Figure.1, Figure. 2 and Figure. 3 respectively.

### 4.2. CASE 2: Vector Sequences and Corresponding Binary Sequences.

For this case also $\mathrm{k}=2$ is chosen.
The simulation study is carried out with seed values of 16 possible $2 \times 1$ vectors over $Z_{4}$ instead of matrices. For $\mathrm{n}=5,10,15,20,25$ and 30 , the corresponding number of $2 \times 2$ coefficient matrices are arbitrarily chosen from a set of 256 possible $2 \times 2$ matrices over $Z_{4}$.

In each case, 10 different sequences of length $\mathrm{m}=5000$ bits are generated after binary transformation of sequences over $\mathrm{Z}_{4}$ as discussed in section 3.1. Linear complexities of these 10 sequences are computed using Berlekamp- Massey algorithm [11].The statistical behavior of linear complexity is found by computing its mean value, variance and standard deviation.The results are tabulated in Table 4.Columns of Table 4 shows the computed linear complexity of 10 sequences generated using recurrence relation of order $\mathrm{n}=5,10,15,20,25$ and 30 respectively. The corresponding mean linear complexity $\mu_{\mathrm{x}}$, variance $\sigma_{\mathrm{x}}{ }^{2}$ and corresponding standard deviation $\sigma_{\mathrm{x}}$ are also listed. From these results it is evident that the linear complexity value is increasing with the order n of recurrence relation and approaches $\mathrm{m} / 2$ for $\mathrm{n} \geq 15$. Correspondingly variance and standard deviation decreases.This implies that the sequence generated have linear complexity almost equal to $\mathrm{m} / 2$ with high probability for $\mathrm{m}=5000$ bits and $\mathrm{n} \geq 15$.
Similarly in Table 5 linear complexities X, mean value of linear complexity $\mu_{\mathrm{x}}$, variance $\sigma_{\mathrm{x}}{ }^{2}$ and corresponding standard deviation $\sigma_{x}$ for sequences of length 10000 bits for $n=5,10,15,20,25$ and 30 are listed.

Likewise in Table 6 linear complexities $X$, mean valueof linear complexity $\mu_{x}$, variance $\sigma_{x}{ }^{2}$ and corresponding standard deviation $\sigma_{x}$ for sequences of length 20000 bits for $n=5,10,15,20,25$ and 30 are also listed. It is seen from Table 5 and Table 6 that for $\mathrm{m}=10000$ and 20000 and for n $\geq 20$ the linear complexity approaches $\mathrm{m} / 2$.

The variation of mean $\mu_{\mathrm{x}}$, variance $\sigma_{\mathrm{x}}{ }^{2}$ and standard deviation $\sigma_{\mathrm{x}}$ with different m and n are depicted in Figure.4, Figure. 5 and Figure.6.respectively for different length of sequence $m$ $=5000,10000$ and 20000. It is seen that the values of variance and standard deviation are decreasing as $n$ increases.

From the above results it is seen that for $\mathrm{n} \geq 15$ the mean value of linear complexity $\mu_{\mathrm{x}}$ is almost equal to $\mathrm{m} / 2$ and hence the generated sequences have linear complexity $\mathrm{m} / 2$ with high probability for $m=5000$ bits. It is also seen that variance $\sigma_{x}{ }^{2}$ and standard deviation $\sigma_{x}$ are small. The same behavior of linear complexity, variance and standard deviation of linear complexity are observed for $\mathrm{m}=10000$ for $\mathrm{n} \geq 20$ and for $\mathrm{m}=20000$. For $\mathrm{n} \geq 30$, linear complexity nearly $\mathrm{m} / 2$.

Figure 6: Plot of Standard Deviation of Linear
Complexity, $\sigma_{\mathrm{x}}{ }^{2} \mathrm{v} / \mathrm{s}$ Number of Stages, $n$ Case I Matrix sequence with $\mathrm{k}=2$

The statistical results $\mu_{\mathrm{x}}, \sigma_{\mathrm{x}}{ }^{2}$ based on 10 trials in each case are used to get the bound on probability of linear complexity X lying within the range $\mu_{\mathrm{x}}-25 \leq \mathrm{X} \leq \mu_{\mathrm{x}}+25$ using Chebychev inequality [20]. First Chebychev inequality as defined in [38] is given below.
$\mathrm{P}\left(\left|\mathrm{X}-\mu_{\mathrm{x}}\right| \geq \delta\right) \leq \sigma_{\mathrm{x}}{ }^{2} / \delta^{2} ; \delta>0$
Where $\mathrm{P}\left(\left|\mathrm{X}-\mu_{\mathrm{x}}\right| \geq \delta\right)$ is the probability that X lies outside the range $\left(\mu_{\mathrm{x}}-\delta\right) \leq \mathrm{X} \leq\left(\mu_{\mathrm{x}}+\delta\right)$. This probability is always less than or equal to $\sigma_{x}^{2} / \delta^{2}$.
Chebychev inequality is generally expressed as in equation (8). It can also be interpreted as,
$\mathrm{P}\left(\left|\mathrm{X}-\mu_{\mathrm{x}}\right| \leq \delta\right) \geq 1-\sigma_{\mathrm{x}}^{2} / \delta^{2} ; \delta>\sigma_{\mathrm{x}}$
where $\mathrm{P}\left(\left|\mathrm{X}-\mu_{\mathrm{x}}\right| \leq \delta\right)$ is the probability that X lies inside the range $\left(\mu_{\mathrm{x}}-\delta\right) \leq \mathrm{X} \leq\left(\mu_{\mathrm{x}}+\delta\right.$ ).This probability is always greater than or equal to $1-\sigma_{\mathrm{x}}{ }^{2} / \delta^{2}$

Equation. 11 is used to observe the change in probability bound with increase in n from 15.The probability bound is computed for $\mathrm{n}=15,20,25$ and 30 using Table 1 to table 6 . In all these cases $\delta$ is taken as 25 .The results are tabulated in Table $7,8,9,10,11$ and 12 , corresponding to matrix and vector recurrence relations.

## 5. Conclusions

Use of matrix recurrence relation (1) and (2) defined over $\mathrm{Z}_{4}$ for the generation of random binary sequences derived from sequences over $\mathrm{Z}_{4}$, results in random sequences with large linear complexity determined using Massey- Berlekamp algorithm. To study the statistical properties of the linear complexity, mean $\mu_{\mathrm{x}}$, variance $\sigma_{\mathrm{x}}{ }^{2}$ and standard deviation $\sigma_{\mathrm{x}}$ are determined by considering randomly chosen sequences of different lengths. Six cases for $n=5,10,15,20,25$ and 30 are considered.In each case sequences of length 5000,10000 and 20000 bits is considered. For each combination of n and m , by randomly chosing different initial matrices and coefficient matrices 10 sequnces are generated and their linear complexity property is investigated.

It is seen from the Tables 7 to12, that for $\mathrm{n} \geq 15$ the probability that the linear complexity X differ by mean value $\mu_{\mathrm{x}}$ by 25 always increases with n and m . For $\mathrm{m}=20000$ and $\mathrm{n}=30$ probability that linear complexity X is within $(10000 \pm 25)$ is always greater than or equal to 0.9977 in case of random binary sequence derived from recursion relation (1). Similarly it is greater than 0.9832 for random binary sequence derived from recursion relation (2).

The proposed method of generation of sequences over $\mathrm{Z}_{4}$ is linear; the corresponding binary sequence with binary conversion $0,1,2,3$ to $00,01,10,11$ respectively turns out to be nonlinear. Hence the linear complexity of the sequence is increased compared to m - sequence. Algorithm is simple with modulo4 arithmetic. It is possible to implement both in hardware and software. There are large choices for number of stages,n initial content ( $U_{i}$ 's or $V_{i}$ 's) of different size and the different coefficient matrices ( $\mathrm{A}_{\mathrm{i}}$ ' s ) which can be chosen to generate large number of sequences.

## Authors

Ramesh $\mathbf{S}$ received the B.E degree in Electronics \& Communication Engineering from Gulbarga University, Karnataka, India in 1990, and M.Tech Degree in Industrial Electronics from Visvesvaraya Technological University, Belgaum, India in 2001 and currently working towards Ph.D Degree at Dr MGR University, Chennai, India. He is working as Faculty in the Department of Electronics \& Communication Engineering, Dr Ambedkar Institute of Technology, Bangalore, India. His research areas include Analog Communication, Digital Communication, Cryptography and VLSI Design.

Dr K N Haribhat received the B.E Degree with honors from Mysore University in 1966, M.Tech and Ph.D in Electronics \& Communication Engineering from Indian Institute of Technology, Kanpur, in 1973 and 1986, respectively. He is currently working as Dean Academic and Head, Department of Electronics \& Communication Engineering at Nagarjuna College of Engineering \& Technology, Bangalore, India. He was with Karnataka Regional
 Engineering College, Suratkal, India (Currently known as NIT-K) for more than 30 years. His research areas include Analog Communication, Digital Communication and Cryptography. He has authored more than 25 papers in National/international Conferences and Journals.He has coauthored two books on communication.

Dr Murali R received the M.Sc Degree in Mathematics from Bangalore University, Karnataka, India in 1990, and Ph.D Degree in Mathematics from Bangalore University, India in 1999 and currently working as Professor in the Department of Mathematics, at Dr Ambedkar Institute of Technology, Bangalore, India. His research areas include Graph Theory-Hamiltonian graphs. He has authored more than 12 papers in National/international Journals.
